Data import and tidying

Week 3

AEM 2850 / 5850 : R for Business Analytics

Cornell Dyson

Spring 2024

Acknowledgements: Grant McDermott, Allison Horst, R4DS (2e)

Announcements

We will not assign any late penalties for the survey and lab-02

Late assignments will be penalized going forward

- If something comes up, please email me and Victor **in advance**

Reminders:

- Submit assignments via canvas
  - Lab-02 was due yesterday (Monday) at 11:59pm

Questions before we get started?

Plan for today

Prologue

Data import

- read_csv
- write_csv
- read_excel

Tidy data

- pivot_longer
- pivot_wider

Summary

Prologue

What are our concentrations?

Take a guess: what's the most common concentration among classmates?

```
## # A tibble: 79 × 2
##    program concentration
##    <chr>   <chr>
##  1 MPS     Finance
##  2 BS      international development; ag
##  3 PhD     Human Behavior and Design
##  4 BS      Business Analytics and International Trade and Development
##  5 BA      Economics
##  6 BS      Agribusiness Management
##  7 BS      Finance
##  8 BS      Sustainable Business and Economic Policy
##  9 BS      Business Analytics
## 10 BS      Business Analytics and Food Industry Management
## # ℹ 69 more rows
```

What are our concentrations?

After some processing to get concentration counts, we get:

```
## # A tibble: 1 × 11
##    acct    ba   dev  econ enviro finance  food  mgmt  mktg other strategy
##   <int> <int> <int> <int>  <int>   <int> <int> <int> <int> <int>    <int>
## 1     3    18     4     8     16      18     2     8     3     9        5
```

What is the "level of observation" in this data frame? (i.e., what are the rows?)

Is the best way to organize concentration counts?

How would you use counts to compute shares in this data frame?

What are our "tidy" concentrations?

Let's `pivot_longer` and `slice_max` to get the top 3:

```
## # A tibble: 3 × 2
##   concentration count
##   <chr>         <int>
## 1 ba               18
## 2 finance          18
## 3 enviro           16
```

How would you use what we learned last week to compute shares?

```
tidy_concentrations |> mutate(share = count / sum(count)) # easy!
```

```
## # A tibble: 3 × 3
##   concentration count share
##   <chr>         <int> <dbl>
## 1 ba               18 0.191
## 2 finance          18 0.191
## 3 enviro           16 0.170
```

Data import

Data import

Plain-text rectangular files are a common way to store and share data:

- comma delimited files (`readr::read_csv`)
- tab delimited files (`readr::read_tsv`)
- fixed width files (`readr::read_fwf`)

We will just cover csv files since `readr` syntax is transferable

Super bowl ads: a csv example

Super bowl ads in csv format

superbowl.csv — Edited

Getting from a csv to a data frame

How are data frames and csv files similar?

- both are rectangular
- csv lines often correspond to rows
- csv commas delineate columns

How are they different?

- csv files do not store column types!

1) readr::read_csv

`read_csv` helps us get from point a to point b:

- you give it the path to your csv file
- it takes the first line of data as column names by default
- it guesses column types and builds up a data frame

Most csv files can be read using the defaults, so we will focus on that

If you run into special cases, consult `?read_csv`

An aside on paths

First we need to figure out what path to give `read_csv`

We have several options:

- absolute paths
  - `/Users/todd/aem2850/slides/data/superbowl.csv`
  - `C:\aem2850\slides\data\superbowl.csv`
- relative paths
  - `data/superbowl.csv`
- links
  - `https://raw.githubusercontent.com/superbowl-ads.csv`
- others
  - see `?read_csv`

An aside on paths

Relative paths are nice: work if you move R code to another directory or device

But what are they relative to?

The working directory

But where is the working directory?

R scripts (.R) in an R Project: default working directory is the project directory

Quarto (.qmd): default working directory is the location of the .qmd file

In our RStudio Cloud projects, these will both be `/cloud/project`, which is the default directory for our projects and where we store our .qmd templates

An aside on paths

More generally, you can check your working directory using `getwd()`

Example: here's the working directory for the slides' source code on my laptop:

```
getwd()
```

```
## [1] "/Users/tdg48/Documents/GitHub/aem2850/content/slides"
```

`setwd()` will alter the working directory

An aside on paths

Just for context, here is a list of (some) directories below the working directory

```
## .
## ├── css
## ├── data
## ├── img
## └── libs
```

Now list (some of) the .csv files in the folder `data`:

```
## data
## └── superbowl.csv
```

`data/superbowl.csv` is the relative path from our working directory to our csv

1) readr::read_csv

So all we need to do is give that relative path to `read_csv`:

```
ads <- read_csv("data/superbowl.csv")
```

```
## Rows: 247 Columns: 25
## ── Column specification ────────────────────────────────────────────────────────
## Delimiter: ","
## chr  (10): brand, superbowl_ads_dot_com_url, youtube_url, id, kind, etag, ti...
## dbl   (7): year, view_count, like_count, dislike_count, favorite_count, comm...
## lgl   (7): funny, show_product_quickly, patriotic, celebrity, danger, animal...
## dttm  (1): published_at
##
## ℹ Use `spec()` to retrieve the full column specification for this data.
## ℹ Specify the column types or set `show_col_types = FALSE` to quiet this message.
```

That was easy!

Now we're back to our old tricks

```
ads |>
  count(funny)
```

```
## # A tibble: 2 × 2
##   funny     n
##   <lgl> <int>
## 1 FALSE    76
## 2 TRUE    171
```

```
ads |>
  group_by(brand) |>
  summarize(likes = sum(like_count, na.rm = TRUE)) |>
  arrange(desc(likes))
```

```
## # A tibble: 10 × 2
##    brand      likes
##    <chr>      <dbl>
##  1 Doritos   326151
##  2 NFL       224263
##  3 Coca-Cola 160231
##  4 Bud Light 104380
##  5 Budweiser  88765
##  6 Pepsi      14796
##  7 Toyota      5316
##  8 Hynudai     4204
##  9 E-Trade     2624
## 10 Kia         2127
```

2) readr::write_csv

Use `write_csv` to write data to a `.csv`:

```
write_csv(ads, "data/superbowl.csv") # overwrite the raw data (bad idea!)

ads |>
  select(year, brand, youtube_url) |>
  write_csv("superbowl-urls.csv") # write modified output to a new file
```

csv is not always the best storage medium

To preserve column specifications and save time when working in R, use `write_rds()` and `read_rds()` to save and open data frames in .RDS format

For multiple objects, `save()` and `load()` are handy functions from base R that work with the .RData format

Importing excel data

Wait, what about getting data from excel spreadsheets?

Use `readxl::read_excel()` for data that is stored in `.xls` or `.xlsx` format

`readxl` isn't loaded as part of the core tidyverse, so we need to load it first:

```
library(readxl) # already installed as part of the tidyverse, but not loaded by default
excel_sheets("data/readxl/datasets.xlsx") # list the sheets in datasets.xlsx
```

```
## [1] "iris"     "mtcars"   "chickwts" "quakes"
```

Importing excel data

```
read_excel("data/readxl/datasets.xlsx", sheet = "mtcars")
```

```
## # A tibble: 32 × 11
##      mpg   cyl  disp    hp  drat    wt  qsec    vs    am  gear  carb
##    <dbl> <dbl> <dbl> <dbl> <dbl> <dbl> <dbl> <dbl> <dbl> <dbl> <dbl>
##  1  21       6  160    110  3.9   2.62  16.5     0     1     4     4
##  2  21       6  160    110  3.9   2.88  17.0     0     1     4     4
##  3  22.8     4  108     93  3.85  2.32  18.6     1     1     4     1
##  4  21.4     6  258    110  3.08  3.22  19.4     1     0     3     1
##  5  18.7     8  360    175  3.15  3.44  17.0     0     0     3     2
##  6  18.1     6  225    105  2.76  3.46  20.2     1     0     3     1
##  7  14.3     8  360    245  3.21  3.57  15.8     0     0     3     4
##  8  24.4     4  147.    62  3.69  3.19  20       1     0     4     2
##  9  22.8     4  141.    95  3.92  3.15  22.9     1     0     4     2
## 10  19.2     6  168.   123  3.92  3.44  18.3     1     0     4     4
## # ℹ 22 more rows
```

Importing excel data

Can also use arguments like `range` to get data using excel lingo

```
read_excel("data/readxl/datasets.xlsx",
           range = "mtcars!A1:D6") # note the combination of sheet and cell range
```

```
## # A tibble: 5 × 4
##     mpg   cyl  disp    hp
##   <dbl> <dbl> <dbl> <dbl>
## 1  21       6   160   110
## 2  21       6   160   110
## 3  22.8     4   108    93
## 4  21.4     6   258   110
## 5  18.7     8   360   175
```

Tidy data

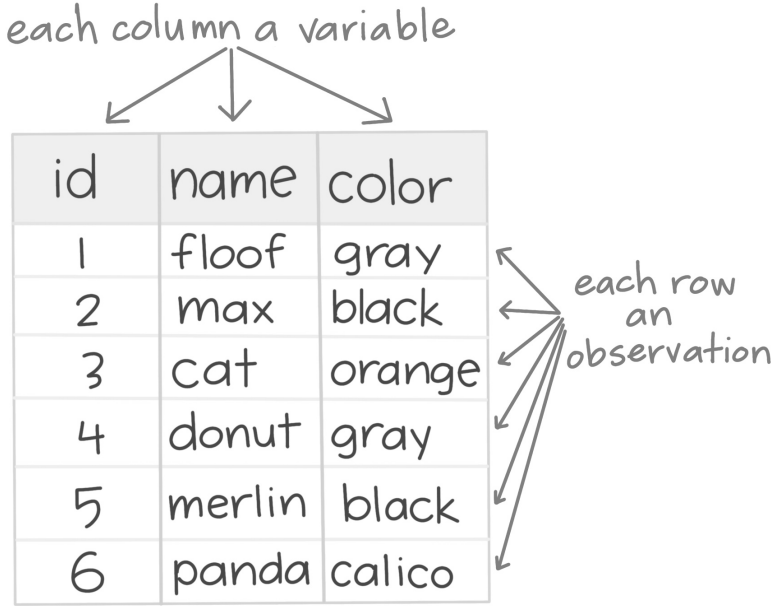
WHAT is "tidy" data?

"TIDY DATA is a standard way of mapping the meaning of a dataset to its structure."

–HADLEY WICKHAM

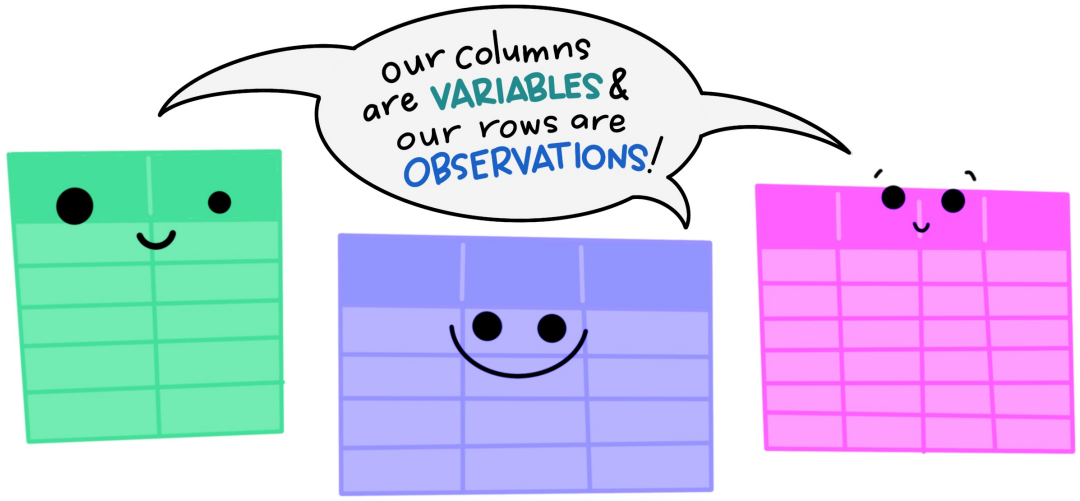
In tidy data:

- each variable forms a column
- each observation forms a row
- each cell is a single measurement



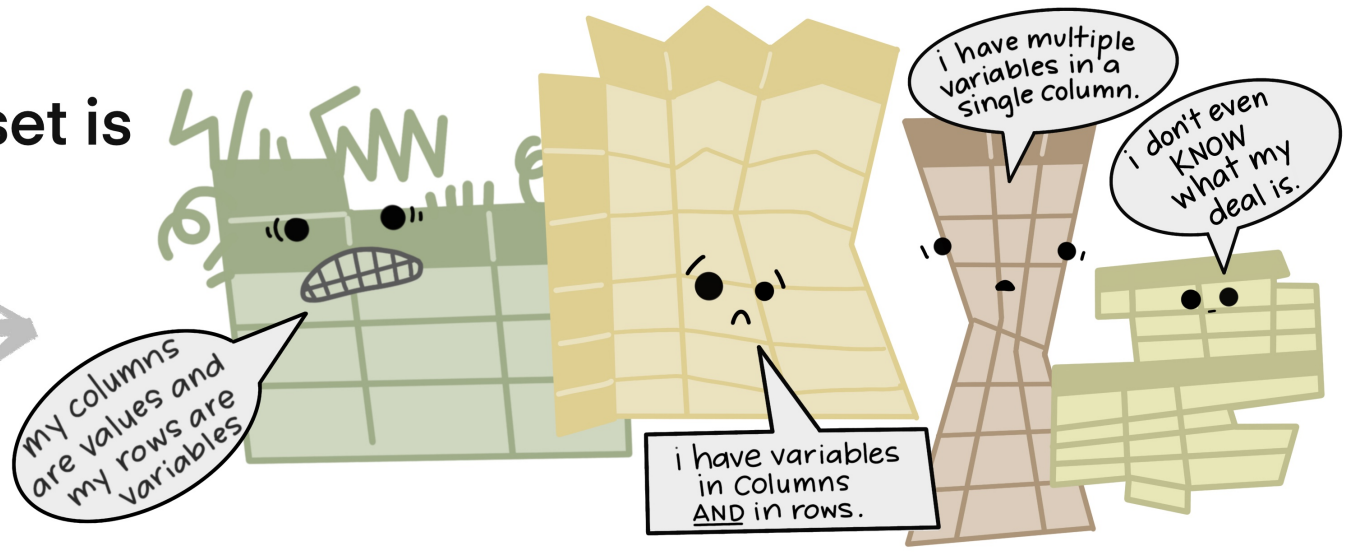
Wickham, H. (2014). Tidy Data. Journal of Statistical Software *59* (10). DOI: 10.18637/jss.v059.i10

The standard structure of tidy data means that "tidy datasets are all alike..."



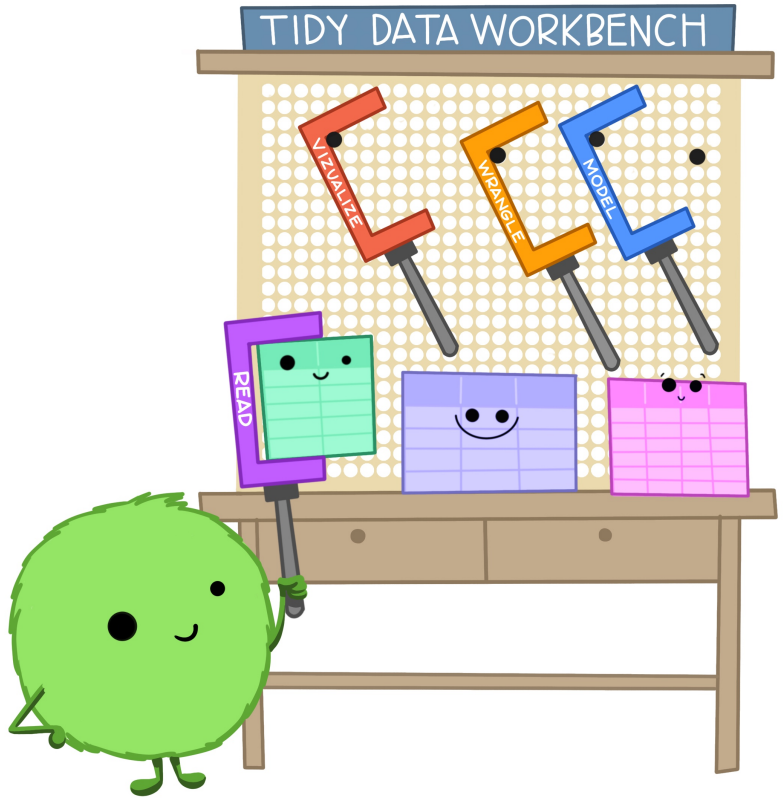
"...but every messy dataset is messy in its own way."

–HADLEY WICKHAM

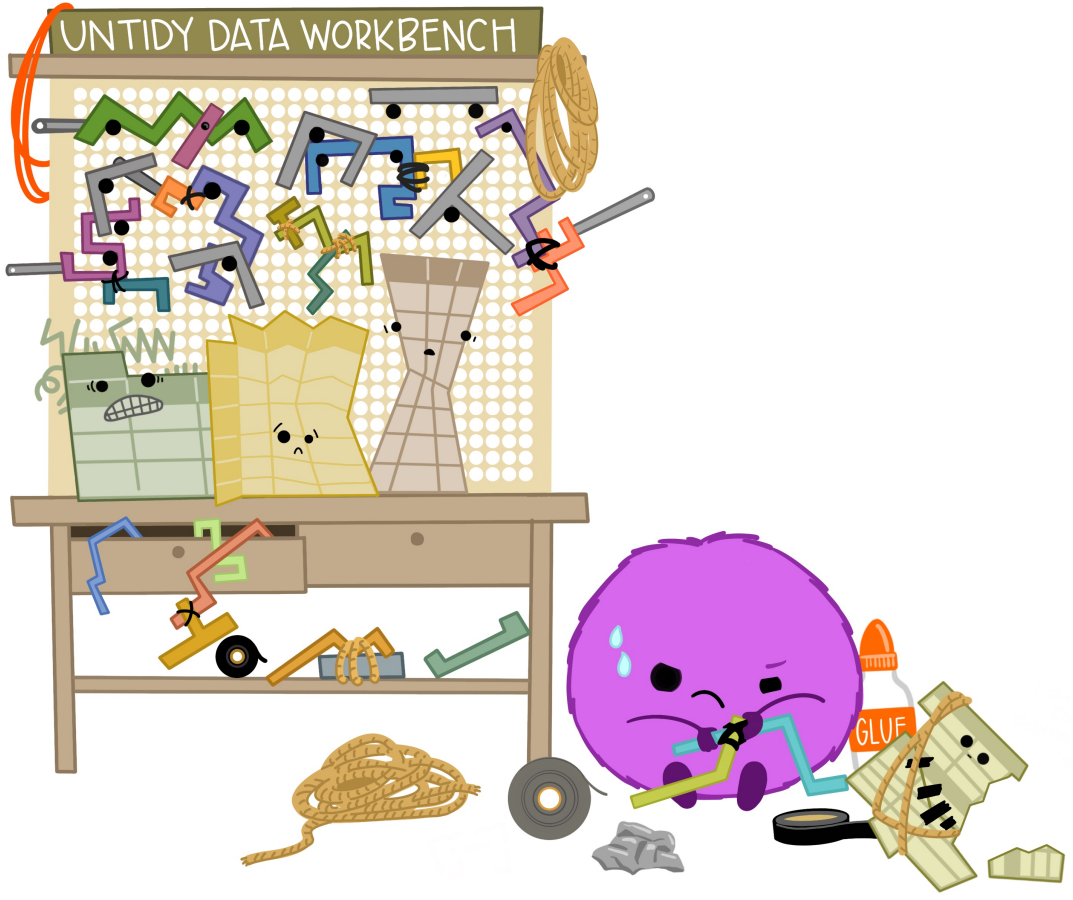


WHY "tidy" data?

When working with tidy data, we can use the same tools in similar ways for different datasets...



...but working with untidy data often means reinventing the wheel with one-time approaches that are hard to iterate or reuse.



Which of these do you think is most tidy?

```
table1
#> # A tibble: 4 × 4
#>   country      year  cases population
#>   <chr>       <dbl>  <dbl>      <dbl>
#> 1 Afghanistan  1999    745   19987071
#> 2 Afghanistan  2000   2666   20595360
#> 3 Brazil       1999  37737  172006362
#> 4 Brazil       2000  80488  174504898
```

```
table2
#> # A tibble: 4 × 3
#>   country      year rate
#>   <chr>       <dbl> <chr>
#> 1 Afghanistan  1999 745/19987071
#> 2 Afghanistan  2000 2666/20595360
#> 3 Brazil       1999 37737/172006362
#> 4 Brazil       2000 80488/174504898
```

```
table3
#> # A tibble: 8 × 4
#>   country      year type            count
#>   <chr>       <dbl> <chr>           <dbl>
#> 1 Afghanistan  1999 cases             745
#> 2 Afghanistan  1999 population  19987071
#> 3 Afghanistan  2000 cases            2666
#> 4 Afghanistan  2000 population  20595360
#> 5 Brazil       1999 cases           37737
#> 6 Brazil       1999 population 172006362
#> # … with 2 more rows
```

Here, `table1`. Though in general, it can depend on your objectives!

Why is `table1` a good choice?

The `dplyr` functions from last week are designed to work with tidy data:

```
# compute rate per 10,000 people
table1 |>
  mutate(rate = cases / population * 10000)
```

```
## # A tibble: 4 × 5
##   country      year cases population  rate
##   <chr>       <dbl> <dbl>      <dbl> <dbl>
## 1 Afghanistan  1999   745   19987071 0.373
## 2 Afghanistan  2000  2666   20595360 1.29
## 3 Brazil       1999 37737  172006362 2.19
## 4 Brazil       2000 80488  174504898 4.61
```

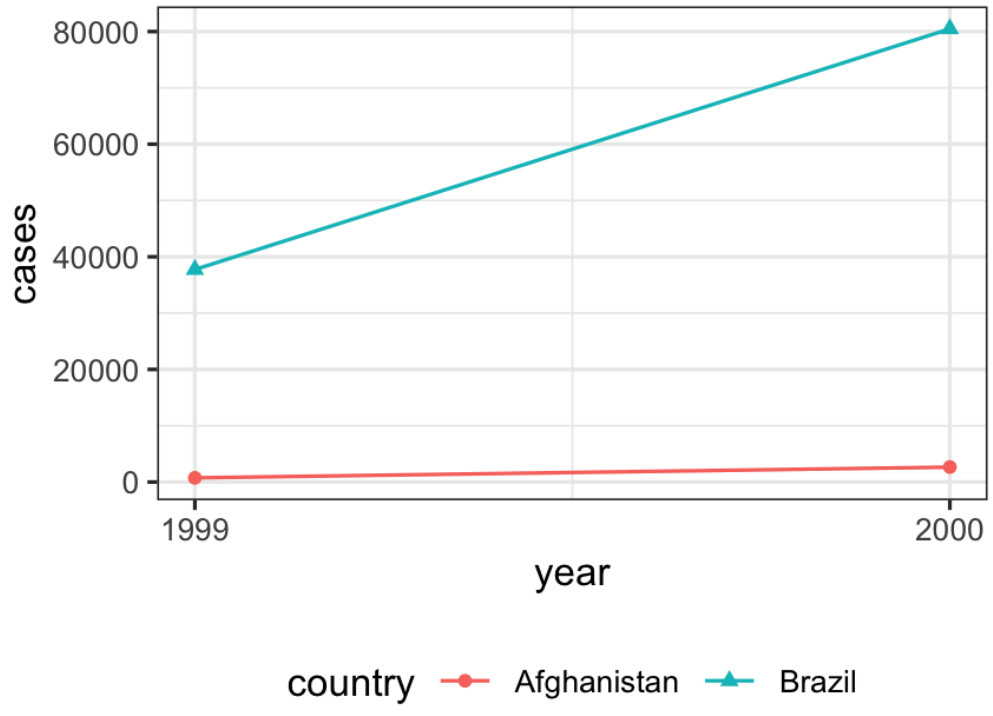
```
# compute cases per year
table1 |>
  group_by(year) |>
  summarize(cases = sum(cases))
```

```
## # A tibble: 2 × 2
##    year cases
##   <dbl> <dbl>
## 1  1999 38482
## 2  2000 83154
```

Why is `table1` a good choice?

The `ggplot2` functions we will learn are designed to work with tidy data:

```
# visualize changes over time
table1 |>
  ggplot(aes(x = year, y = cases)) +
  geom_line(aes(color = country)) +
  geom_point(aes(color = country,
                 shape = country)) +
  scale_x_continuous(breaks = c(1999, 2000)) +
  theme_bw() +
  theme(legend.position = "bottom")
```



HOW can we "tidy" data?

Key tidyr verbs

1. `pivot_longer`: Pivot wide data into long format
2. `pivot_wider`: Pivot long data into wide format

Let's start with an untidy dataset

```
stocks
```

```
## # A tibble: 2 × 4
##   date        AAPL  GOOG  MSFT
##   <date>     <dbl> <dbl> <dbl>
## 1 2024-02-06  209.  149.  412.
## 2 2024-02-05  211.  145.  364.
```

We have 4 columns, the date and the stocks

Why do I think this is untidy?

1. stock names `AAPL`, `GOOG`, `MSFT` are values, not variables
2. cells contain prices, but there is no variable `price`

1) tidyr::pivot_longer

Let's use `pivot_longer()` to get this in tidy form

We want to pivot the stock name columns `AAPL`, `GOOG`, `MSFT` "longer"

We need to give three key pieces of information to `pivot_longer()`:

1. **Which columns to pivot** using `AAPL:MSFT` or `-date`
2. **What variable will hold the names:** `names_to = "stock"`
3. **What variable will hold the values:** `values_to = "price"`

Here is what that syntax looks like:

```
stocks |>
  pivot_longer(cols = AAPL:MSFT, names_to = "stock", values_to = "price")
```

1) tidyr::pivot_longer

Here is what that syntax does:

```
stocks |> pivot_longer(cols = AAPL:MSFT, names_to = "stock", values_to = "price")
```

```
## # A tibble: 6 × 3
##   date       stock price
##   <date>     <chr> <dbl>
## 1 2024-02-06 AAPL   209.
## 2 2024-02-06 GOOG   149.
## 3 2024-02-06 MSFT   412.
## 4 2024-02-05 AAPL   211.
## 5 2024-02-05 GOOG   145.
## 6 2024-02-05 MSFT   364.
```

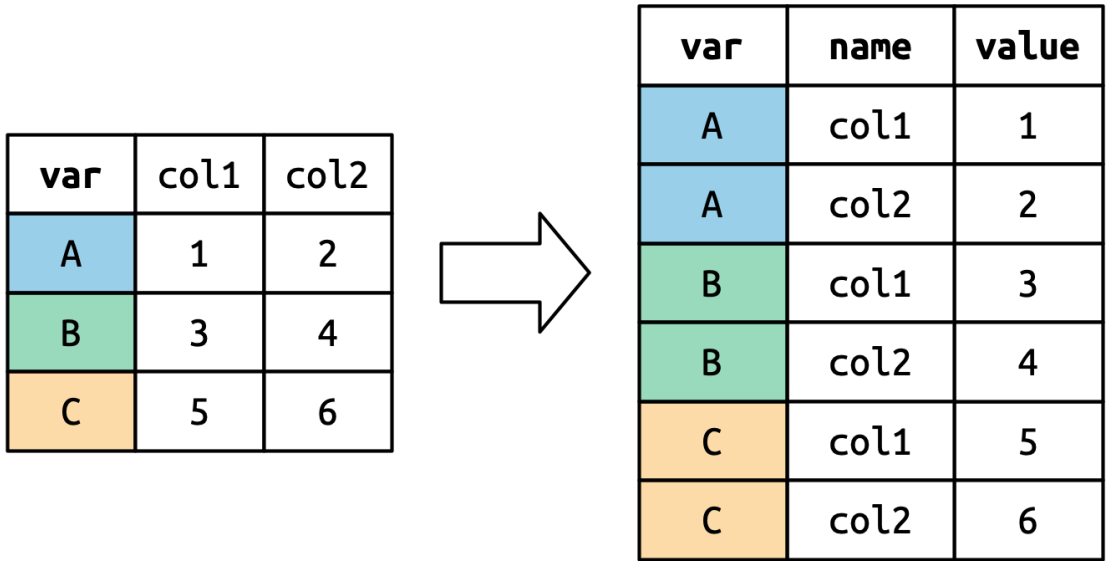
Let's save the "tidy" (i.e., long) stocks data frame for later use

```
tidy_stocks <- stocks |>
  pivot_longer(cols = -date, names_to = "stock", values_to = "price")
```

1) tidyr::pivot_longer: How does it work?

```
df |>
  pivot_longer(
    cols = col1:col2,
    names_to = "name",
    values_to = "value"
  )
```

Existing variables such as `var` need to be repeated, once for each column in `cols`



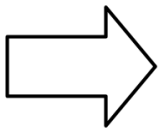
1) tidyr::pivot_longer: How does it work?

```
df |>
  pivot_longer(
    cols = col1:col2,
    names_to = "name",
    values_to = "value"
  )
```

Column names become values in a new variable, whose name is given by `names_to`

- repeated once for each row in the original

var	col1	col2
A	1	2
B	3	4
C	5	6

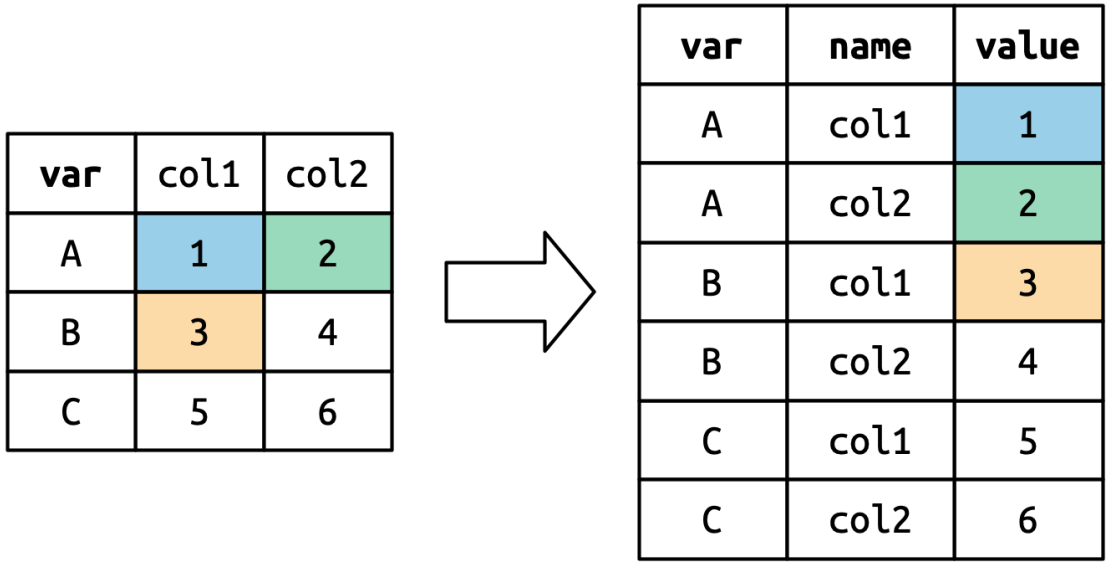


var	name	value
A	col1	1
A	col2	2
B	col1	3
B	col2	4
C	col1	5
C	col2	6

1) tidyr::pivot_longer: How does it work?

```
df |>
  pivot_longer(
    cols = col1:col2,
    names_to = "name",
    values_to = "value"
  )
```

Cell values become values in a new variable, with a name given by `values_to`



2) tidyr::pivot_wider

We can use `pivot_wider()` to make data "wide"

Let's say we want to convert `tidy_stocks` back to `stocks`

```
tidy_stocks
```

```
## # A tibble: 6 × 3
##   date       stock price
##   <date>     <chr> <dbl>
## 1 2024-02-06 AAPL   209.
## 2 2024-02-06 GOOG   149.
## 3 2024-02-06 MSFT   412.
## 4 2024-02-05 AAPL   211.
## 5 2024-02-05 GOOG   145.
## 6 2024-02-05 MSFT   364.
```

```
stocks
```

```
## # A tibble: 2 × 4
##   date        AAPL  GOOG  MSFT
##   <date>     <dbl> <dbl> <dbl>
## 1 2024-02-06  209.  149.  412.
## 2 2024-02-05  211.  145.  364.
```

2) tidyr::pivot_wider

```
tidy_stocks
```

```
## # A tibble: 6 × 3
##   date       stock price
##   <date>     <chr> <dbl>
## 1 2024-02-06 AAPL   209.
## 2 2024-02-06 GOOG   149.
## 3 2024-02-06 MSFT   412.
## 4 2024-02-05 AAPL   211.
## 5 2024-02-05 GOOG   145.
## 6 2024-02-05 MSFT   364.
```

We need to give two key pieces of information to `pivot_wider()`:

1. **What variable to get names from:**
   `names_from = "stock"`
2. **What variable to get values from:**
   `values_from = "price"`

`pivot_wider()` figures out the rest

2) tidyr::pivot_wider

```
tidy_stocks |> pivot_wider(names_from = stock, values_from = price)
```

```
## # A tibble: 2 × 4
##   date        AAPL  GOOG  MSFT
##   <date>     <dbl> <dbl> <dbl>
## 1 2024-02-06  209.  149.  412.
## 2 2024-02-05  211.  145.  364.
```

We just got our original data back!

```
stocks
```

```
## # A tibble: 2 × 4
##   date        AAPL  GOOG  MSFT
##   <date>     <dbl> <dbl> <dbl>
## 1 2024-02-06  209.  149.  412.
## 2 2024-02-05  211.  145.  364.
```

2) tidyr::pivot_wider

```
tidy_stocks |> pivot_wider(names_from = date, values_from = price)
```

```
## # A tibble: 3 × 3
##   stock `2024-02-06` `2024-02-05`
##   <chr>        <dbl>        <dbl>
## 1 AAPL          209.         211.
## 2 GOOG          149.         145.
## 3 MSFT          412.         364.
```

Reversing the arguments effectively transposed the original data

```
stocks
```

```
## # A tibble: 2 × 4
##   date        AAPL  GOOG  MSFT
##   <date>     <dbl> <dbl> <dbl>
## 1 2024-02-06  209.  149.  412.
## 2 2024-02-05  211.  145.  364.
```

tidyr resources

Data tidying with tidyr : : CHEATSHEET

Vignette (from the **tidyr** package)

```
vignette("tidy-data")
```

Ch. 5 of R for Data Science (2e)

Original paper (Hadley Wickham, 2014 JSS)

Summary

Key verbs so far

Import

readr

1. `read_csv`
2. `write_csv`

readxl

1. `read_excel`

Tidy

tidyr

1. `pivot_longer`
2. `pivot_wider`

Transform

dplyr

1. `filter`
2. `arrange`
3. `select`
4. `mutate`
5. `summarize`
